1 Problem

In 1926, Fock noted [1, 2, 3] that Schrödinger’s equation for an electric charge $e$ of mass $m$ in electromagnetic fields described by potentials $A_{\mu} = (V, A)$ can be written, in Gaussian units with $c$ as the speed of light,

$$\frac{(-i\hbar D)^2}{2m} \psi = i\hbar D_0 \psi,$$

using the “altered” (covariant) derivative $D_\mu = \partial_\mu - ieA_\mu/\hbar c$, (1)

which is gauge invariant only if the gauge transformation of the potentials, $A_\mu(x_\nu) \rightarrow A_\mu + \partial_\mu \chi(x_\nu)$, is accompanied by a phase change of the wavefunction, $\psi(x_\nu) \rightarrow e^{-ie\chi(x_\nu)/c} \psi$. Yang and Mills (1954) [4, 5] may have been the first to point out that Fock’s argument can be inverted such that a requirement of local phase invariance of the form $\psi(x_\nu) \rightarrow e^{-ie\chi(x_\nu)/c} \psi$ implies the existence of an interaction described by a potential $A_\mu$ (and charge $e$) which satisfies gauge invariance and modifies Schrödinger’s equation via the altered derivative $D_\mu$. This led to a greater appreciation of the significance of potentials in the quantum realm.

Separately, Aharonov and Bohm (1959) [6, 7] discussed an electron that moves only outside a long solenoid magnet (where $B = 0$ to a good approximation; see the sketch below, from [6]), and which accumulates a different phase in its wavefunction depending on which side of the magnet it passes.\(^1\) The resulting interference pattern, which depends on the (gauge-invariant) magnetic flux in the solenoid (that can be related to the vector potential $A$ in whatever gauge is used), has been observed in subsequent experiments [12]-[22].\(^2\)

![Sketch of the Aharonov-Bohm experiment](image)

The quantum interference effect in the Aharonov-Bohm experiment is impressive, but there are already disconcerting issues in purely classical considerations thereof. It is often

\(^1\)The concept of the Aharonov-Bohm effect was to some extent anticipated in considerations of effects in electron microscopy [8]-[11].

\(^2\)This result is often misinterpreted as evidence that the vector potential $A$ is “observable” in the quantum realm. A better statement is that there exist quantum-electrodynamic effects on the behavior of an electron which moves only in a region of zero external electric and magnetic field, but where the vector potential (in any choice of gauge) is nonzero. Note that the observed result relates directly to the magnetic field $B_{\text{solenoid}}$ although this field is zero at the electron; the paradox is more that the observed quantum effect seems to be action-at-a-distance (as bothered E-P-R in another context [23]) between the solenoid and the electron.
remarked that there is no classical effect on an electron that passes outside a long solenoid magnet, where $B_{\text{solenoid}} = 0$. However, the current density that generates the solenoid field is affected by the magnetic field of the moving electron (even assuming that the electric charge density associated with the current density is zero).

**Problem:** Deduce the force on a solenoid of radius $a$ about the $z$-axis that carries azimuthal surface current density $K_\phi = I$ per unit length, when an electron of velocity $v = v \hat{y}$ is at position $(x, y, z) = (b, vt, 0)$, where $v \ll c$ and $|b| \gg a$.

That is, Newton’s third law is not obeyed by this configuration!

Issues like this were noted by Ampère in the 1820’s and led him to doubt the existence of isolated, moving electric charges, which view put particle physics on hold for 60 years (in England but not in Germany). Only after Poynting (1884) [24] developed the notion that electromagnetic fields can support a flux of energy (and hence also contain momentum [25, 26, 27]), did (English) physicists have the confidence to reconsider the concept of elementary charged particles.

In retrospect we note that the issue of apparent violation of Newton’s third law could have been resolved earlier, based on Faraday’s insight that what we now call the Coulomb-gauge vector potential $A^{(C)}$ (called the “electrotonic state” by Faraday\(^7\)) can be associated with “electromagnetic momentum”, as formulated mathematically by Maxwell [35]. In Gaussian units, the electromagnetic momentum associated with a charge distribution $\varrho$ that is immersed in a vector potential $A^{(C)}$ (in the Coulomb gauge\(^8\)) is given (for quasistatic motion) by,

$$P_{\text{EM}} = \int \frac{\varrho A^{(C)}}{c} dVol.$$ (2)

The Faraday-Maxwell form (2) is a classical effect of the solenoid on the electron, but it does not imply that the vector potential is observable in classical electrodynamics. Rather, we

---

\(^3\)Aug. 28, 2022. If the solenoid is made of a conductive material, the electron induces a charge separation on the surface of the solenoid, giving it an electric dipole moment. Then, the electric dipole field exerts a classical force on the electron. As such, demonstrations like that in [20, 21], which used a superconducting solenoid, do not represent the Aharonov-Bohm effect in its purest form.

Experiments using electron microscopes, such as [13]-[15] use electrostatic focusing of the electron beam, and so are also not considered by “purists” to have studied the “true” Aharonov-Bohm effect.

\(^4\)Assume that the magnetic field of the electron is not “shielded” by the solenoid, which shielding would imply additional currents that create additional magnetic field external to the solenoid that lead to a force on the moving electron.

\(^5\)An important first step was taken by Thomson in 1881 [28, 29] based on considerations of kinetic energy of a moving charge.

\(^6\)Germans since Weber (1846) [30] had considered theories of “point” electric charges.

\(^7\)Faraday first speculated on an electro-tonic state in Art. 60 of [31]. Other mentions by Faraday of the electrotonic state include Art. 1661 of [32], Arts. 1729 and 1733 of [33], and Art. 3269 of [34].

\(^8\)The Coulomb-gauge vector potential $A^{(C)}$ is “rotational” (or “solenoidal” or “transverse”), meaning that $\nabla \cdot A^{(C)} = 0$. In a general gauge, the vector potential can be written (using Helmholtz’ theorem [37]) as $A = A_{\text{irr}} + A_{\text{rot}}$ where $\nabla \times A_{\text{irr}} = 0$ and $\nabla \cdot A_{\text{rot}} = 0$. Then, a gauge transformation $A \rightarrow A' = A + \nabla \chi$, $V \rightarrow V' = V - \partial \chi / \partial t$, where $V$ is the electric scalar potential and $\chi$ is the gauge-transformation function, implies that $A'_{\text{irr}} = A_{\text{irr}} + \nabla \chi$ and $A'_{\text{rot}} = A_{\text{rot}}$ if $\nabla^2 \chi \neq 0$, but $A'_{\text{irr}} = A_{\text{irr}}$ and $A'_{\text{rot}} = A_{\text{rot}} + \nabla \chi$ if $\nabla^2 \chi = 0$ (for example, if $\chi = xy$). That is, contrary to the claim of eq. (B.16), p. 17, of [38], the rotational part of the vector potential is not gauge invariant (and the Coulomb-gauge vector potential is not unique for a given current density). See also Appendix B of [37].
note that it is equivalent to the Poynting-Thomson-Poincaré form, \( \mathbf{P}_{EM} = \int \mathbf{E} \times \mathbf{B} \, d\text{Vol}/4\pi c \), as shown, for example, in [36]. While the Faraday-Maxwell form for the electromagnetic momentum suggests that this resides with the electron, the Poynting-Thomson-Poincaré form suggests that it resides in the electromagnetic fields. This classical ambiguity is a preview of the Aharonov-Bohm effect that an electron can be affected by an electromagnetic field elsewhere than at the electron.

**Problem:** Use eq. (2) to deduce the electromagnetic momentum of the electron + solenoid when the electron is at \((x, y, z) = (b, vt, 0)\), and from this show that \(d\mathbf{P}_{EM}/dt\) is equal and opposite to the force on the solenoid found previously.

This seems to be a satisfactory resolution to the issue of momentum conservation, but a disconcerting result remains. Suppose the electric charge were at rest; then the electromagnetic momentum (2) is nonzero, while the solenoid is at rest also and seems to contain no net momentum. Hence, we have an example of a system at rest which seems to contain nonzero total momentum!

Peculiarities of this sort were dramatized by Shockley in 1967 [39], and remain an arcane aspect of classical physics, where some systems contain “hidden” momentum [44] (such that systems “at rest” indeed have zero total momentum). One can give a plausible classical model of the “hidden” momentum as residing in the electrical current in the present example [45]. Perhaps the main significance of the “hidden” momentum for the Aharonov-Bohm effect is to remind us that even in a “classical” view, the electron is “entangled” with the solenoid, although the magnetic field of the solenoid happens to be zero at the location of the electron. While the field of the solenoid has no “classical” effect on the electron, the electron does have a “classical” effect on the solenoid, so the two objects should not be regarded as independent entities. In this context, it should be pleasing, rather than disturbing, that in the quantum realm the solenoid has an effect on the electron.

**Extended Problem:** Comment also on energy and angular momentum in this system.

In the author’s view, the Aharonov-Bohm effect (and the related debate about the “observability” of potentials [48]) misses the point that the role of the potentials (which must obey gauge invariance), combined with the notion of local phase invariance, is to determine the form of the interactions of elementary particles. It is the nonobservability of the potentials, because they are subject to gauge transformations, which leads the potentials to be included in the altered derivative \(D_\mu\), eq. (1), that makes them so important in the development of the theory of elementary particles and fields.

A classical analog of a subtle aspect of the Aharonov-Bohm effect is discussed in [50].

---

9These peculiarities were previously noted by J.J. Thomson in 1904 [29, 40, 41, 42], but were little discussed by others for many years. A partial awareness of classical “paradoxes” in the Aharonov-Bohm effect appeared in [43].

10This theme was developed by Aharonov for the “dual” example in which a loop of current (magnetic dipole) interacts with a line charge parallel to the axis of the loop [46]. See also [47].

11For a similar commentary, which includes demonstration that the Aharonov-Bohm effect vanishes in a suitable classical limit, see [49].
2 Solution

2.1 Momentum

The magnetic field $B_e$ at position $\mathbf{x}$ of an electron of charge $-e$ and velocity $\mathbf{v}$ at position $\mathbf{x}_e$ is (in Gaussian units, and for $v \ll c$),

$$B_e(\mathbf{x}, \mathbf{x}_e) = \frac{\mathbf{v}}{c} \times E_e(\mathbf{x}, \mathbf{x}_e) = -\frac{e\mathbf{v} \times \mathbf{R}}{cR^3}, \quad \text{where} \quad \mathbf{R} = \mathbf{x} - \mathbf{x}_e. \quad (3)$$

The force of this magnetic field from an electron at $(x, y, z)$ on a solenoidal (surface) current density $K(x, y, z)$ is (in Gaussian units, and for $e = \theta$)

$$\mathbf{F} = \int \frac{\mathbf{K} \times \mathbf{B}_s}{c} \, d\text{Area}$$

2.1.1 Momentum

This force is very small, being of order $1/c^2$, and clarification of its possible effect on the system is more of “academic” than practical interest. Note that $\pi a^2 I/c$ is the magnetic moment per unit length along the solenoid.

The uniform magnetic field $\mathbf{B}_\text{solenoid} = B \hat{\mathbf{z}}$ inside the solenoid has magnitude $B = 4\pi I/c$, as follows from Ampère’s law. This field can also be deduced from a (coulomb-gauge) vector potential $\mathbf{A}^{(C)}$ whose only nonzero component in a cylindrical coordinate system $(r, \phi, z)$ is $A_{\phi}^{(C)}(r)$, where $\mathbf{B} = \nabla \times \mathbf{A}^{(C)}$ implies for a loop of radius $r$ that,

$$\oint \mathbf{A}^{(C)} \cdot d\mathbf{l} = 2\pi r A_{\phi}^{(C)} = \int \nabla \times \mathbf{A}^{(C)} \cdot d\text{Area} = \mathbf{B} \cdot d\text{Area} = \frac{4\pi^2 I}{c} \begin{cases} r^2 & (r < a), \\
2a^2 & (r > a). \end{cases} \quad (5)$$
Outside the solenoid, the magnetic field is zero (in the limit of an infinite solenoid), while the vector potential can be taken as the form,\(^\text{12}\)

\[
A_{\phi}^{(C)}(r > a) = \frac{2\pi a^2 I}{cr}, \quad A^{(C)}(r > a) = \frac{2\pi a^2 I}{cr^2}(-y, x, 0),
\]

which also follows from the static form,

\[
A^{(C)}(r) = \int \frac{J(r')}{c|\mathbf{r} - \mathbf{r}'|} d\text{Vol}'.
\]

According to eq. (2) of Faraday and Maxwell, the system of electron plus solenoid has electromagnetic momentum,\(^\text{13}\)

\[
P_{\text{EM}}^{(1)} = -\frac{eA^{(C)}(b, vt, 0)}{c} = -\frac{2\pi a^2 eI}{c^2(b^2 + v^2t^2)}(-vt, b, 0).
\]

The time derivative of this is,

\[
\frac{dP_{\text{EM}}}{dt} = -\frac{2\pi a^2 eIv}{c^2(b^2 + v^2t^2)} \left[ -1 + \frac{2v^2t^2}{b^2 + v^2t^2} \cdot \frac{-2bvt}{b^2 + v^2t^2}, 0 \right]
\]

\[
= \frac{2\pi a^2 eIv}{c^2(b^2 + v^2t^2)} \left[ \frac{b^2 - v^2t^2}{b^2 + v^2t^2} \cdot \frac{2bvt}{b^2 + v^2t^2}, 0 \right] = -\mathbf{F} = -\frac{dP_{\text{mech}}}{dt},
\]

on comparison with eq. (4). Thus,

\[
\frac{dP_{\text{total}}}{dt} = \frac{dP_{\text{EM}}}{dt} + \frac{dP_{\text{mech}}}{dt} = 0,
\]

and the total momentum of the system is constant in time. The electrical current in the solenoid carries momentum, but naïvely we expect that the total mechanical momentum of a current loop would be zero; however, this is not the case if the current loop is subject to an external electric field, as in the present example.

\(^\text{12}\)Other choices for the vector potential \(A\) are possible. In particular, use of the Poincaré gauge leads to an \(A\) that is nonzero only in a region that depends on the (arbitrary) choice of origin [51], so that while it can be said that the charge interacts “locally” with the vector potential, the location of the “local” interaction is not uniquely determined.

Even the Coulomb-gauge vector potential is not unique, as the restricted gauge transformation \(A'^{(C)} = A^{(C)} + \nabla \chi\), \(V'^{(C)} = V^{(C)} - \partial \chi / \partial t\) with \(\nabla^2 \chi = 0\) generates new potentials also in the Coulomb gauge (see sec. IIIC of [52]). For example, \(\chi = \pm Bxy/2\) leads from eq. (6) to the Coulomb-gauge potentials (often attributed to Landau) for an infinite solenoid, \(A^{(C)}(r > a) = \frac{2\pi I}{c} \left[ \frac{\hat{y}}{2} \left( 1 + \frac{v^2}{\rho^2} \right) \hat{\mathbf{x}} \pm \frac{\hat{\mathbf{x}}}{2} \left( 1 + \frac{v^2}{\rho^2} \right) \hat{y} \right].\)

One might argue that the currents which generate the infinite solenoid are purely azimuthal, so the vector potential should respect this symmetry, as is the case for eq. (6). However, this usage of symmetry is not part of the usual notion of electromagnetic potentials.

\(^\text{13}\)The form \(P_{\text{EM}} = -eA^{(C)}/c\) for the electromagnetic momentum is not generally gauge invariant. However, if the current density is static, and (unlike for an infinite solenoid) nonzero only in a bounded region, and one insists that the vector potential vanish at infinity, then rotational part of the vector potential, \(A_{\text{rot}}\), equals the “standard” Coulomb-gauge vector potential of eq. (7). See Appendix B.1 of [37]. That is, the form \(P_{\text{EM}} = -eA^{(C)}/c\) is gauge invariant in a limited sense.
The unbalanced force of the moving electron on the solenoid serves to change its “hidden” internal mechanical momentum, while the bulk of the solenoid remains at rest as the electron passes by.\textsuperscript{14,15}

For completeness, we evaluate the electromagnetic momentum according to the Poynting-Thomson-Poincaré prescription (ignoring the self-field-momentum of the moving electron),

\[
P_{\text{EM}}^{(2)} = \int \frac{\mathbf{E}_e \times \mathbf{B}_{\text{solenoid}}}{4\pi c} \, d\text{Vol} = \frac{1}{4\pi c} \int_{-\infty}^{\infty} \pi a^2 c^2 dz \frac{-e(-b,-vt,z)}{(b^2 + v^2 t^2 + z^2)^{3/2}} \times \frac{4\pi I(0,0,1)}{c},
\]

as in eq. (8).

It turns out\textsuperscript{[36, 60]} there is a third way that the electromagnetic momentum can be computed (for quasistatic examples) based on the Coulomb-gauge electric scalar potential \( V^{(C)} \) and the current density \( \mathbf{J} \),

\[
P_{\text{EM}}^{(3)} = \int \frac{V^{(C)} \mathbf{J}}{c^2} \, d\text{Vol} = \int \frac{V^{(C)} \mathbf{K}}{c^2} \, d\text{Area}
\]

For a discussion of the character of the “hidden” mechanical momentum in a current loop, see\textsuperscript{[45, 59]}.

\[ \text{The fact that electromagnetic momentum can be computed several different ways reminds us that even in “classical” systems the subsystems should be regarded as “entangled” rather than “independent”.} \]

\subsection*{2.2 Energy}

The system of electron plus solenoid has an interaction field energy,

\[
U_{\text{EM, int}} = \frac{\pi a^2 I}{4\pi c} \int_{-\infty}^{\infty} \mathbf{E}_e \cdot \mathbf{E}_{\text{solenoid}} + \mathbf{B}_e \cdot \mathbf{B}_{\text{solenoid}} \, d\text{Vol} \approx \frac{\pi a^2 I}{c} \int_{-\infty}^{\infty} B_e(0,0,z) \, dz
\]

\[ \text{for a discussion of the character of the “hidden” mechanical momentum in a current loop, see [45, 59].} \]
since $E_{\text{solenoid}} = 0$ and $B_{\text{solenoid}} = 4\pi I \hat{z}/c$ with magnetic flux $\Phi_{\text{sol}} = \pi a^2 B_{\text{solenoid}}$. That is, the electromagnetic interaction field energy (which can have either sign) is greatest in magnitude when the electron is closest to the solenoid.

Where is the compensating energy such that the total energy of the (isolated) system is conserved?

In the Aharonov-Bohm effect it is tacitly assumed that the magnetic field of the solenoid does not change with time, and it is typically implied that this is because that field is due to permanent magnetism. For example, the uniform surface current density $K_\phi = I$ considered on p. 2 could be due to a cylinder of radius $a$ with uniform magnetization density $\mathbf{M} = I \hat{z}/c$.

In this case, there is an additional interaction energy,

$$U_{M,\text{int}} = -\int \mathbf{M} \cdot \mathbf{B}_e \, d\text{Vol} \approx -\frac{\pi a^2 I}{c} \int_{-\infty}^{\infty} \mathbf{B}_e(0,0,z) \, dz = -U_{\text{EM, int}}, \quad (14)$$

such that the total interaction energy is zero.$^{16,17}$

However, it could be that the solenoid is made of a conductive material and the surface currents are maintained constant by a battery. In this case, the battery does work on the currents (and \textit{vice versa}) such that the sum of the field energy and that of the battery remains constant. One way to see this is to take the time derivative of eq. (13),$^{18}$

$$\frac{dU_{\text{EM, int}}}{dt} = \int \frac{\partial \mathbf{B}_e}{\partial t} \cdot \mathbf{B}_{\text{solenoid}} \frac{1}{4\pi} \, d\text{Vol} = -\frac{c}{4\pi} \int (\nabla \times \mathbf{E}_e) \cdot \mathbf{B}_{\text{solenoid}} \, d\text{Vol} = -\int \mathbf{J}_{\text{solenoid}} \cdot \mathbf{E}_e \, d\text{Vol}, \quad (15)$$

using the identity that $\nabla \cdot (\mathbf{E} \times \mathbf{B}) = \mathbf{B} \cdot (\nabla \times \mathbf{E}) - \mathbf{E} \cdot (\nabla \times \mathbf{B})$. That is the change in the interaction field energy is opposite to the work done by the field $\mathbf{E}_e$ on the currents. To keep the currents constant, the battery must do work on them opposite to that done by $\mathbf{E}_e$, which means that the change of energy of the battery equals the work done by $\mathbf{E}_e$ on the currents, which is opposite to the change in the field energy.

We might worry that the “hidden” momentum invoked in sec. 2.1 is associated with a “hidden” energy that should be considered here. However, as discussed in [45], “hidden” mechanical momentum can be thought of as arising because the total energy of the charge carriers of the current in an external electric field remains constant; if the electric potential energy of the charge rises, the kinetic energy (and momentum) decreases, \textit{etc.}

---

$^{16}$A delicacy is that if the solenoid does not move, no work is done on it by the field $\mathbf{B}_e$, so eq. (14) does not obviously represent a stored energy. However, in case of a permanent solenoid magnet, the meaning of the interaction energy (13) is also doubtful in that one cannot well represent permanent magnetism by a classical current density $\mathbf{J}$. That the energies (13) and (14) cancel for a permanent solenoid magnet is a “classical” accommodation of an ultimately quantum phenomenon.

See also secs. 5.7 and 5.16 of [55].

$^{17}$Mar. 3, 2022. An argument was made in [56] that the interaction field energy is only given by our eq. (13), which is time dependent, and hence the kinetic energy/velocity of the electron must also be time dependent such that total energy is conserved. This argument was disputed in [57, 58], but the compensating term (14) for the case of a permanent magnet was not displayed, which had left it open to some views that the argument of [56] might still be valid.

$^{18}$This argument was suggested by D.J. Griffiths.
2.3 Angular Momentum

The force (4) of the electron on the solenoid is associated with a torque,

\[
\tau = \int r \times \frac{K \times B_e}{c} \, d\text{Area}
\]

\[
= -\frac{Iev}{c^2} \int_{-\infty}^{\infty} \, dz \int_{0}^{2\pi} \, a \, d\phi \, \frac{r \times (-\sin \phi, \cos \phi, 0) \times \{ \hat{y} \times [(a \cos \phi, a \sin \phi, z) - (b, vt, 0)] \}}{[(a \cos \phi - b)^2 + (a \sin \phi - vt)^2 + z^2]^{3/2}}
\]

\[
= -\frac{aIev}{c^2} \int_{-\infty}^{\infty} \, dz \int_{0}^{2\pi} \, \phi \, d\phi \, \frac{r \times (-\sin \phi, \cos \phi, 0) \times (z, 0, b - a \cos \phi)}{(a^2 + b^2 + v^2t^2 - 2ab \cos \phi - 2avt \sin \phi + z^2)^{3/2}}
\]

\[
= -\frac{aIev}{c^2} \int_{0}^{2\pi} \, d\phi \int_{-\infty}^{\infty} \, dz \frac{(a \cos \phi, a \sin \phi, z) \times [\cos \phi(b - a \cos \phi), \sin \phi(b - a \cos \phi), -z \cos \phi]}{(a^2 + b^2 + v^2t^2 - 2ab \cos \phi - 2avt \sin \phi + z^2)^{3/2}}
\]

\[
= -\frac{aIev}{c^2} \int_{0}^{2\pi} \, d\phi \int_{-\infty}^{\infty} \, dz \frac{(-bz \sin \phi, bz \cos \phi, 0)}{(a^2 + b^2 + v^2t^2 - 2ab \cos \phi - 2avt \sin \phi + z^2)^{3/2}} = 0. \quad (16)
\]

Since the solenoid exerts no force/torque on the electron, the total torque on the system is zero and we expect its angular momentum to be constant in time.\(^{19}\)

The system of uniformly moving electron plus constant-field solenoid contains both field and mechanical angular momentum. The mechanical angular momentum of the electron is constant in time.

It is delicate to compute the field angular momentum, in that the calculation requires assigning a location to the field momentum. The three prescriptions, (8), (11) and (12) which gave the same value for the total field momentum suggest different locations for it, and hence lead to different values for the field momentum.

The field angular momentum can be computed from eq. (8) as,

\[
L_{\text{EM}}^{(1)} = r_e \times P_{\text{EM}}^{(1)} = -\frac{r_e \times eA^{(C)}}{c} = -(b, vt, 0) \times \frac{2\pi a^2 Ie(-vt, b, 0)}{c^2(b^2 + v^2t^2)} = -\frac{2\pi a^2 Ie \hat{z}}{c^2}, \quad (17)
\]

which is constant in time. Using eq. (11) we find,

\[
L_{\text{EM}}^{(2)} = \int r \times \frac{E_e \times B_{\text{solenoid}}}{4\pi c} \, d\text{Vol}
\]

\[
\approx \frac{1}{4\pi c} \int_{a}^{a} \, r \, dr \int_{0}^{2\pi} \, d\phi \int_{-\infty}^{\infty} \, dz \, (r \cos \phi, r \sin \phi, z) \times
\]

\[
- e(r \cos \phi - b, r \sin \phi - vt, z) \frac{1}{[(r \cos \phi - b)^2 + (r \sin \phi - vt)^2 + z^2]^{3/2}} \times \frac{4\pi I(0, 0, 1)}{c}
\]

\[
= -\frac{Ie}{c^2} \int_{-\infty}^{\infty} \, dz \int_{0}^{a} \, r \, dr \int_{0}^{2\pi} \, d\phi \frac{[z(r \cos \phi - b), z(r \cos \phi - b), rb \cos \phi + rvt \sin \phi - r^2]}{(z^2 + b^2 + v^2t^2 - 2rb \cos \phi - 2rvt \sin \phi + r^2)^{3/2}}
\]

\[
\approx -\frac{Ie}{c^2} \int_{-\infty}^{\infty} \, dz \int_{0}^{a} \, r \, dr \int_{0}^{2\pi} \, d\phi \frac{(0, 0, rb \cos \phi + rvt \sin \phi)}{(z^2 + b^2 + v^2t^2)^{3/2}} \left(1 + 3\frac{rb \cos \phi + rvt \sin \phi}{z^2 + b^2 + v^2t^2}\right)
\]

\(^{19}\)In the case where the solenoid is a cylinder of uniform magnetization density \(M\) the net torque of the electron’s magnetic field on the magnetization is zero (although there is a bending moment).
\[
\begin{align*}
&= -\frac{Ie}{c^2} \int_{-\infty}^{\infty} \frac{dz}{z^2 + (b^2 + v^2 t^2)^{5/2}} \int_0^a r \, dr \, 3\pi r^2 (b^2 + v^2 t^2) \\
&= -\frac{\pi a^4 Ie(0,0,1)}{c^2 (b^2 + v^2 t^2)} = -\frac{\pi a^4 Ie \mathbf{z}}{c^2 (b^2 + v^2 t^2)},
\end{align*}
\]
which varies with time. For completeness, we use eq. (12) to obtain,
\[
L^{(3)}_{EM} = \int r \times \frac{V^{(C)}(C)}{c^2} d\text{Vol} = \int r \times \frac{V^{(C)}(C)K}{c^2} d\text{Area}
\]
\[
\begin{align*}
&= -\frac{Ie}{c^2} \int_{-\infty}^{\infty} dz \int_0^{2\pi} a \, d\phi \frac{(a \cos \phi, a \sin \phi, z) \times (z \cos \phi, -z \sin \phi, a)}{[(a \cos \phi - b)^2 + (a \sin \phi - vt)^2 + z^2]^{1/2}} \\
&= -\frac{aIe}{c^2} \int_{-\infty}^{\infty} dz \int_0^{2\pi} d\phi \frac{(z^2 + b^2 + v^2 t^2 - 2ab \cos \phi - 2a vt \sin \phi + a^2)^{1/2}}{(z^2 + b^2 + v^2 t^2)^{1/2}} \int_0^{2\pi} d\phi (0,0,1) \left(1 + \frac{ab \cos \phi + avt \sin \phi}{z^2 + b^2 + v^2 t^2}\right) \\
&= \frac{-2\pi a^2 Ie(0,0,1)}{c^2} \int_{-\infty}^{\infty} \frac{dz}{(z^2 + b^2 + v^2 t^2)^{1/2}} \int_{-\infty}^{\infty} \frac{dz}{(z^2 + b^2 + v^2 t^2)^{1/2}} = L^{(1)}_{EM} \int_{-\infty}^{\infty} \frac{dz}{(z^2 + b^2 + v^2 t^2)^{1/2}},
\end{align*}
\]
which diverges.

Only the field angular momentum (17) is constant in time.

It is surprising that the form (18) is time dependent, since it might seem the most basic form of for the field angular momentum. The computation in eq. (18) ignored the magnetic field outside the long solenoid, although this field is not strictly zero, just extremely small. It turns out that while the “return flux” outside the solenoid can be ignored in computations of the field momentum, this is not the case when calculation the field angular momentum where the field momentum density is multiplied by the vector \( \mathbf{r} \). A more careful computation [61] of \( L^{(2)}_{EM} \) shows that it is the same as \( L^{(1)}_{EM} \), i.e., constant in time.

Indeed, a general result (Appendix B of [61]) is that for quasistatic systems, \( L^{(1)}_{EM} = L^{(2)}_{EM} \) (for suitably careful evaluation of the latter) but that the form \( L^{(3)}_{EM} \) differs from these two. Hence, we identify the field angular momentum in the present example with the result of eq. (17).

Additional subtleties arise when we consider “hidden” momentum and “hidden” angular momentum. We found in sec. 2.1 that the solenoid must contain (small) “hidden” mechanical momentum that is equal and opposite to the time-varying field momentum (11). Associated with this “hidden” mechanical momentum is “hidden” mechanical angular momentum, but the computation of the latter is also delicate as there is no requirement that the sum of the “hidden” mechanical and field angular momenta be zero. See, for example, sec. 4.15 of [44].

Even more subtleties arise if one considers the present example in the rest frame of the electron, such that the solenoid is in motion. In this frame the solenoid appears to have an electric dipole moment [62], and the field of the electron exerts a torque on this moment (whereas there is no such torque in the lab frame). This “paradoxical” torque on an object with a magnetic moment that moves in an electric field is associated with the changing “hidden” mechanical angular momentum of the system, as discussed in [54] for a closely related example.
A Appendix: The Electric Aharonov-Bohm Effect

(Aug. 25, 2022)

The first example considered by Aharonov and Bohm was not the now-familiar case of an electron passing a long solenoid magnet, as on p. 1 above, but an electron that passes through two long, hollow, conducting tubes, as sketched below (from [6]).

![Diagram of electron passing through two conducting tubes](image)

There are no “external” electric or magnetic fields anywhere, except where the electron is near the center of a tube, during which time a charge separation is applied between the two tubes. This results in no “external” force on the electron in the limit of very long tubes, but, in the Coulomb gauge, there exist nonzero (time-dependent) scalar and vector potentials at the position of the charge. Hence, there is a quantum phase difference between the two paths, ABDF and ACEF, of the electron given by (in Gaussian units; see p. 486 of [6]),

\[
\Delta \phi = \frac{e}{\hbar} \oint_{ABDFEC} \left( V \, dt - \frac{A}{c} \cdot dl \right).
\]

Aharonov and Bohm supposed that the contribution of the vector potential to the phase difference could be neglected in this example (in the Coulomb gauge), and implied that an observation of the phase difference (via a shifted diffraction pattern on a screen at F) would provide evidence that the scalar potential \( V \) is “physical”.23

However, we could also work in the Gibbs gauge,24 where the scalar potential \( V \) is zero everywhere, and the phase difference is computed from the vector potential only. That is, the electric Aharonov-Bohm effect does not provide evidence that the scalar potential is a “physical effect”.

And as mentioned in footnote 12 above, the freedom to choose different gauges, leading to different values of the vector potential at the position of the electron, means that the

---

22However, there is an “induced” force on the electron due to the surface charge density on the conducting tubes induced by the electron itself. This force exists both when the electron is outside the tubes, and also inside them unless the electron’s path is exactly down the center of a tube.

23An experiment claiming to have observed the electric Aharonov-Bohm effect [63]-[67] did not use conducting tubes, but a long bimetallic wire that had a static surface charge distribution associate with the contact potential between the two half cylinders of aluminum and platinum. Hence, there was an electrostatic force on the electron as it passed around the wire. This shifted the single-slit diffraction pattern as well as the double-slit pattern, and so is not considered by many to be a true demonstration of the Aharonov-Bohm effect. However, it seems to this author that any experiment on the electric Aharonov-Bohm effect will involve nonzero “classical” forces on the electron.

Another experiment that was sensitive to the electric Aharonov-Bohm effect [68] did not claim to have made a clear separation between “quantum” and “classical” effects.

Studies of a magneto-electric Aharonov-Bohm effect were reported in [69].

24First considered by Gibbs in 1896 [70], and now sometimes called the temporal gauge. See, for example, sec. VIII of [71].
vector potential should also not be regarded as “physical” or “observable”. The observable Aharonov-Bohm effects depends only on certain differences in the potentials, \textit{i.e.}, on the “physical” electric and magnetic fields. Of course, it remains disconcerting that quantum effects such as the (magnetic) Aharonov-Bohm effect can be “nonlocal” in the sense that the electron’s quantum behavior is affected by \( E \) and \( B \) fields at points other than the location of the electron (which goes against the classical view of Faraday and Maxwell of “local” field theory).\(^{25}\)

\(^{25}\) Quantum “nonlocality” famously bothered Einstein [72], and led Bell to formulate his “inequality” [73], whose violation in certain experiments is said to prove that Nature is “nonlocal” in some sense.
